mechanical, electronic, computer and information system based elements. Representative examples are a robot, a washing machine and a computer printer. To be able to evolve such products and work in multidisciplinary teams, a very clear understanding of flow of material, energy and information is needed; points of observation and places of interfaces to outside systems need to be specified. As compared to well-established products, these new products require to be evolved from the concept to function to design to prototyping and testing stages. Due to increasing short life of product designs, these processes have to be carried out in ever decreasing time spans. This can be achieved often by resorting to model-based computer simulation, virtual prototyping and rapid prototyping techniques. Computer simulation requires mathematical model of the system to be built with all the interacting components and it leads to design development and optimization; virtual prototyping helps in designing real world interfaces and spatial description. Rapid prototyping helps in actual testing of the product. A systems-based approach to mechanical design helps in carrying out all these activities. Finally, an application of "A Case Study" method is followed. the electrical properties of materials are emphasized; in addition, topics are selected in order to explain the operation of devices having applications (or possible future applications) in engineering. The mathematics, kept deliberately to a minimum, is well within the grasp of a second-year student. This is achieved by choosing the simplest model that can display the essential properties of a phenomenon, and then examining the difference between the ideal and the actual behaviour. The whole text is designed as an undergraduate course. However most individual sections are self contained and can be used as background reading in graduate courses, and for interested persons who want to explore advances in microelectronics, lasers, nanotechnology and several other topics that impinge on modern life.

### **Design Analysis of Thermal Systems**

Microcomputers are having, and will have in the future, a significant impact on the technology of all fields of engineering. The applications of micro computers of various types that are now integrated into engineering include computers and programs for calculations, word processing, and graphics. The focus of this book is on still another objective—that of control. The forms of microcomputers used in control range from small boards dedicated to control a single device to microcomputers that oversee the operation of numerous smaller computers in a building complex or an industrial plant. The most dramatic growth in control applications recently has been in the microcomputers dedicated to control functions in

automobiles, appliances, production machines, farm machines, and almost all devices where intelligent decisions are profitable. Both engineering schools and individual practicing engineers have responded in the past several years to the dramatic growth in microcomputer control applications in thermal and mechanical systems. Universities have established courses in computer control in such departments of engineering as mechanical, civil, agricultural, chemical and others. Instructors and students in these courses see a clear role in the field that complements that of the computer specialist who usually has an electrical engineering or computer science background. The nonEE or nonCS person should first and foremost be competent in the mechanical or thermal system being controlled. The objectives of extending familiarity into the computer controller are (1) to learn the characteristics, limitations, and capabilities.

**Author Biography:**Dr Vahid Vakiloroya is a mechanical engineer with fourteen years of research experience in the engineering discipline. He received his PhD in mechanical engineering from University of Technology, Sydney. He is currently a research fellow at Western Sydney University and the Director of two engineering companies. Vahid has published extensively in several prestigious journals and has authored a number of international conference papers. He has also published 11 engineering books and a book chapter that focus on heating, ventilation and air conditioning (HVAC) system design and implementation. Prompted by his practical research and development achievements, Vahid was recently selected as top 50 most innovative engineers in Australia by Engineers Australia. He also received the Sir George Julius Medal from Engineers Australia. He won the Excellence in HVAC and Refrigeration Research Award by AIRAH; and was selected as the Green Hero at UTS due to his work on HVAC energy efficiency.

**Book Description:**Conventional HVAC systems rely heavily on energy generated from fossil fuels, which are being rapidly depleted. This - together with a growing demand for cost-effective infrastructure and appliances - has necessitated new installations and major retrofits in occupied buildings to achieve energy efficiency and environmental sustainability. As such, the development of clean energy air conditioning units remains an urgent engineering challenge. Solar HVAC systems, which convert thermal energy into cool air, are known to be an efficient source of heating and cooling. Unlike traditional HVAC systems, solar air conditioning units produce maximum cooling capacity when the sun is

fierce; that is, they are most efficient during the hottest part of the day, in stark contrast to traditional air conditioning units, which are less effective as temperatures increase. This book represents a synergetic framework of system identification, design, development and performance evaluation for a newly-configured air conditioning system to target energy efficiency and environmental sustainability in buildings. In this study, we have originally designed and developed a single-effect lithium bromide (LiBr)-water absorption air-conditioning system, in which hot water is fully supplied by vacuum solar collectors without using any other energy sources such as gas or electricity. The water-cooled condenser of the chiller is supported by a cross-flow cooling tower. In this system, by using water as the working fluid (refrigerant), one can avoid the use of ozone-depletion chlorofluorocarbons and hydro chlorofluorocarbons. Thermodynamic and heat transfer models for absorption chiller components are described in detail. Using these models, a computer simulation software named ABSYS is developed to design the absorption chiller and drive its optimum operating conditions. Thermodynamic design data for single-effect absorption chillers are presented together with the possible combinations of the operating temperatures and the corresponding concentrations in the absorber and generator. The effect of various operating conditions on the performance and output of the absorption refrigeration system are then evaluated. Another computer code is developed by using TRNSYS to evaluate the transient performance of the entire system. Several field tests are carried out to

demonstrate the technical feasibility of the system. The utilisation of the solar energy as the heat input to the generator of the absorption chiller is reported. This proposed design can be helpful to accelerate a global clean society to achieve its sustainable targets. Target Audience: Mechanical engineers, Building service engineers, Researchers and Students, HVAC manufacturers.
